

IMPORTANT

Please follow these instructions to maintain the warranty of your Centerforce® product!

Flywheels: All Centerforce® clutches need to be installed on a clean, properly resurfaced or brand new flywheel. Flywheels must be within original equipment specifications. Centerforce clutches are designed to be used on flywheels made of cast iron, steel, or aluminum with steel inserts.

Break-In: All Centerforce clutches require a break-in period of 450-500 miles of stop-and-go street driving before applying full engine power. This period is required to properly seat the disc with the pressure plate and flywheel.

Balance: All Centerforce clutches are balanced from the factory to meet or exceed Original Equipment (O.E.) specifications. Balancing with the Centerforce weights installed on the clutch assembly may cause an out-of-balance condition. Removing the weights without permission from Centerforce may void the warranty.

Centrifugal Weight System: If your new Centerforce clutch is equipped with the patented centrifugal weight system, do not remove the ring, weights, or spring wire retaining the weight system to the diaphragm fingers. If your Centerforce clutch does not include the centrifugal weight system, it is because there is not sufficient clearance for Centerforce to safely & effectively install the centrifugal weight system.

Aftermarket Hydraulic Release Bearings: When using an aftermarket hydraulic release bearing it is important to check for proper clearance between the bearing and the centrifugal weight system. Some aftermarket hydraulic bearings have an anti-rotator pin that may come into contact with the centrifugal weight system.

Failure to follow the above procedures will void your warranty and may result in decreased performance and/or premature wear!

Possible Flywheel Balance Problem..***

We have found that after having the flywheel surfaced, the flywheel balance may be affected. The flywheel balance should be checked by a qualified balance shop and corrected if out of factory tolerance, prior to the reinstallation of the flywheel and new clutch assembly.

If the flywheel is out of balance, the CENTERFORCE® weight system may shift off center and cause engagement and/or release problems.

Attention Jeep Owners!

Diagnosing possible causes of clutch noise: Squeaky clutch fork, bad bearing retainer collar and/or damaged throw out bearing clips

Inspect your transmission bearing retainer collar prior to installing your new clutch assembly. A worn bearing retainer collar will cause excessive wear to the diaphragm fingers of your pressure plate, heavy clutch pedal effort, squeaky clutch pedal and premature throw out bearing failure. To help prevent this from occurring ensure you have sufficient grease applied to the bearing retainer collar and fill the grease groove in your new throw out bearing.

Inspect your clutch fork for wear. A worn clutch fork will allow the throw out bearing to move side to side within the clutch fork causing noise. Your clutch fork should hold the throw out bearing securely in place.

Inspect the throw out bearing retainer clips when attaching to the clutch fork. Make sure the clips are not bent upward away from the throw out bearing ears/tabs. If the clips are bent, the clips will not secure the throw out bearing properly to the clutch fork allowing the throw out bearing to move freely causing noise.

Inspect your pivot ball for any signs of wear. A worn pivot ball will allow the clutch fork to move freely on the pivot ball which could result in noise.

Replace all worn parts as needed.
